Perinatal outcomes in a cohort of surrogacy pregnancies at a fertility clinic in Colombia.

Camacho AM. Fetal Medicine Experts.

Introduction

to determine perinatal outcomes in a cohort of surrogacy pregnancies in a fertility clinic in Colombia..

Methods:

A prospective descriptive study was conducted to determine the perinatal outcomes of pregnancies undergoing fertility treatment with a surrogate mother in a fertility center in Bogotá.

Results:

A total of 49 pregnant women were treated, with an average age of 34 years. All cases involved in vitro fertilization with egg donation, using frozen eggs. Twenty-one percent of pregnant women delivered before week 37. Two cases of ventricular septal defect, one case of hypospadias, and one case of clubfoot were documented

Conclusion

Surrogacy has a high incidence of preterm birth. Further controlled studies are needed to confirm these findings.
