Introduction

Since the beginning of the millennium, the global trend has been toward delaying motherhood. Studies on this topic have shown that this situation is associated with worse maternal and neonatal outcomes. We propose to review a cohort of our cases

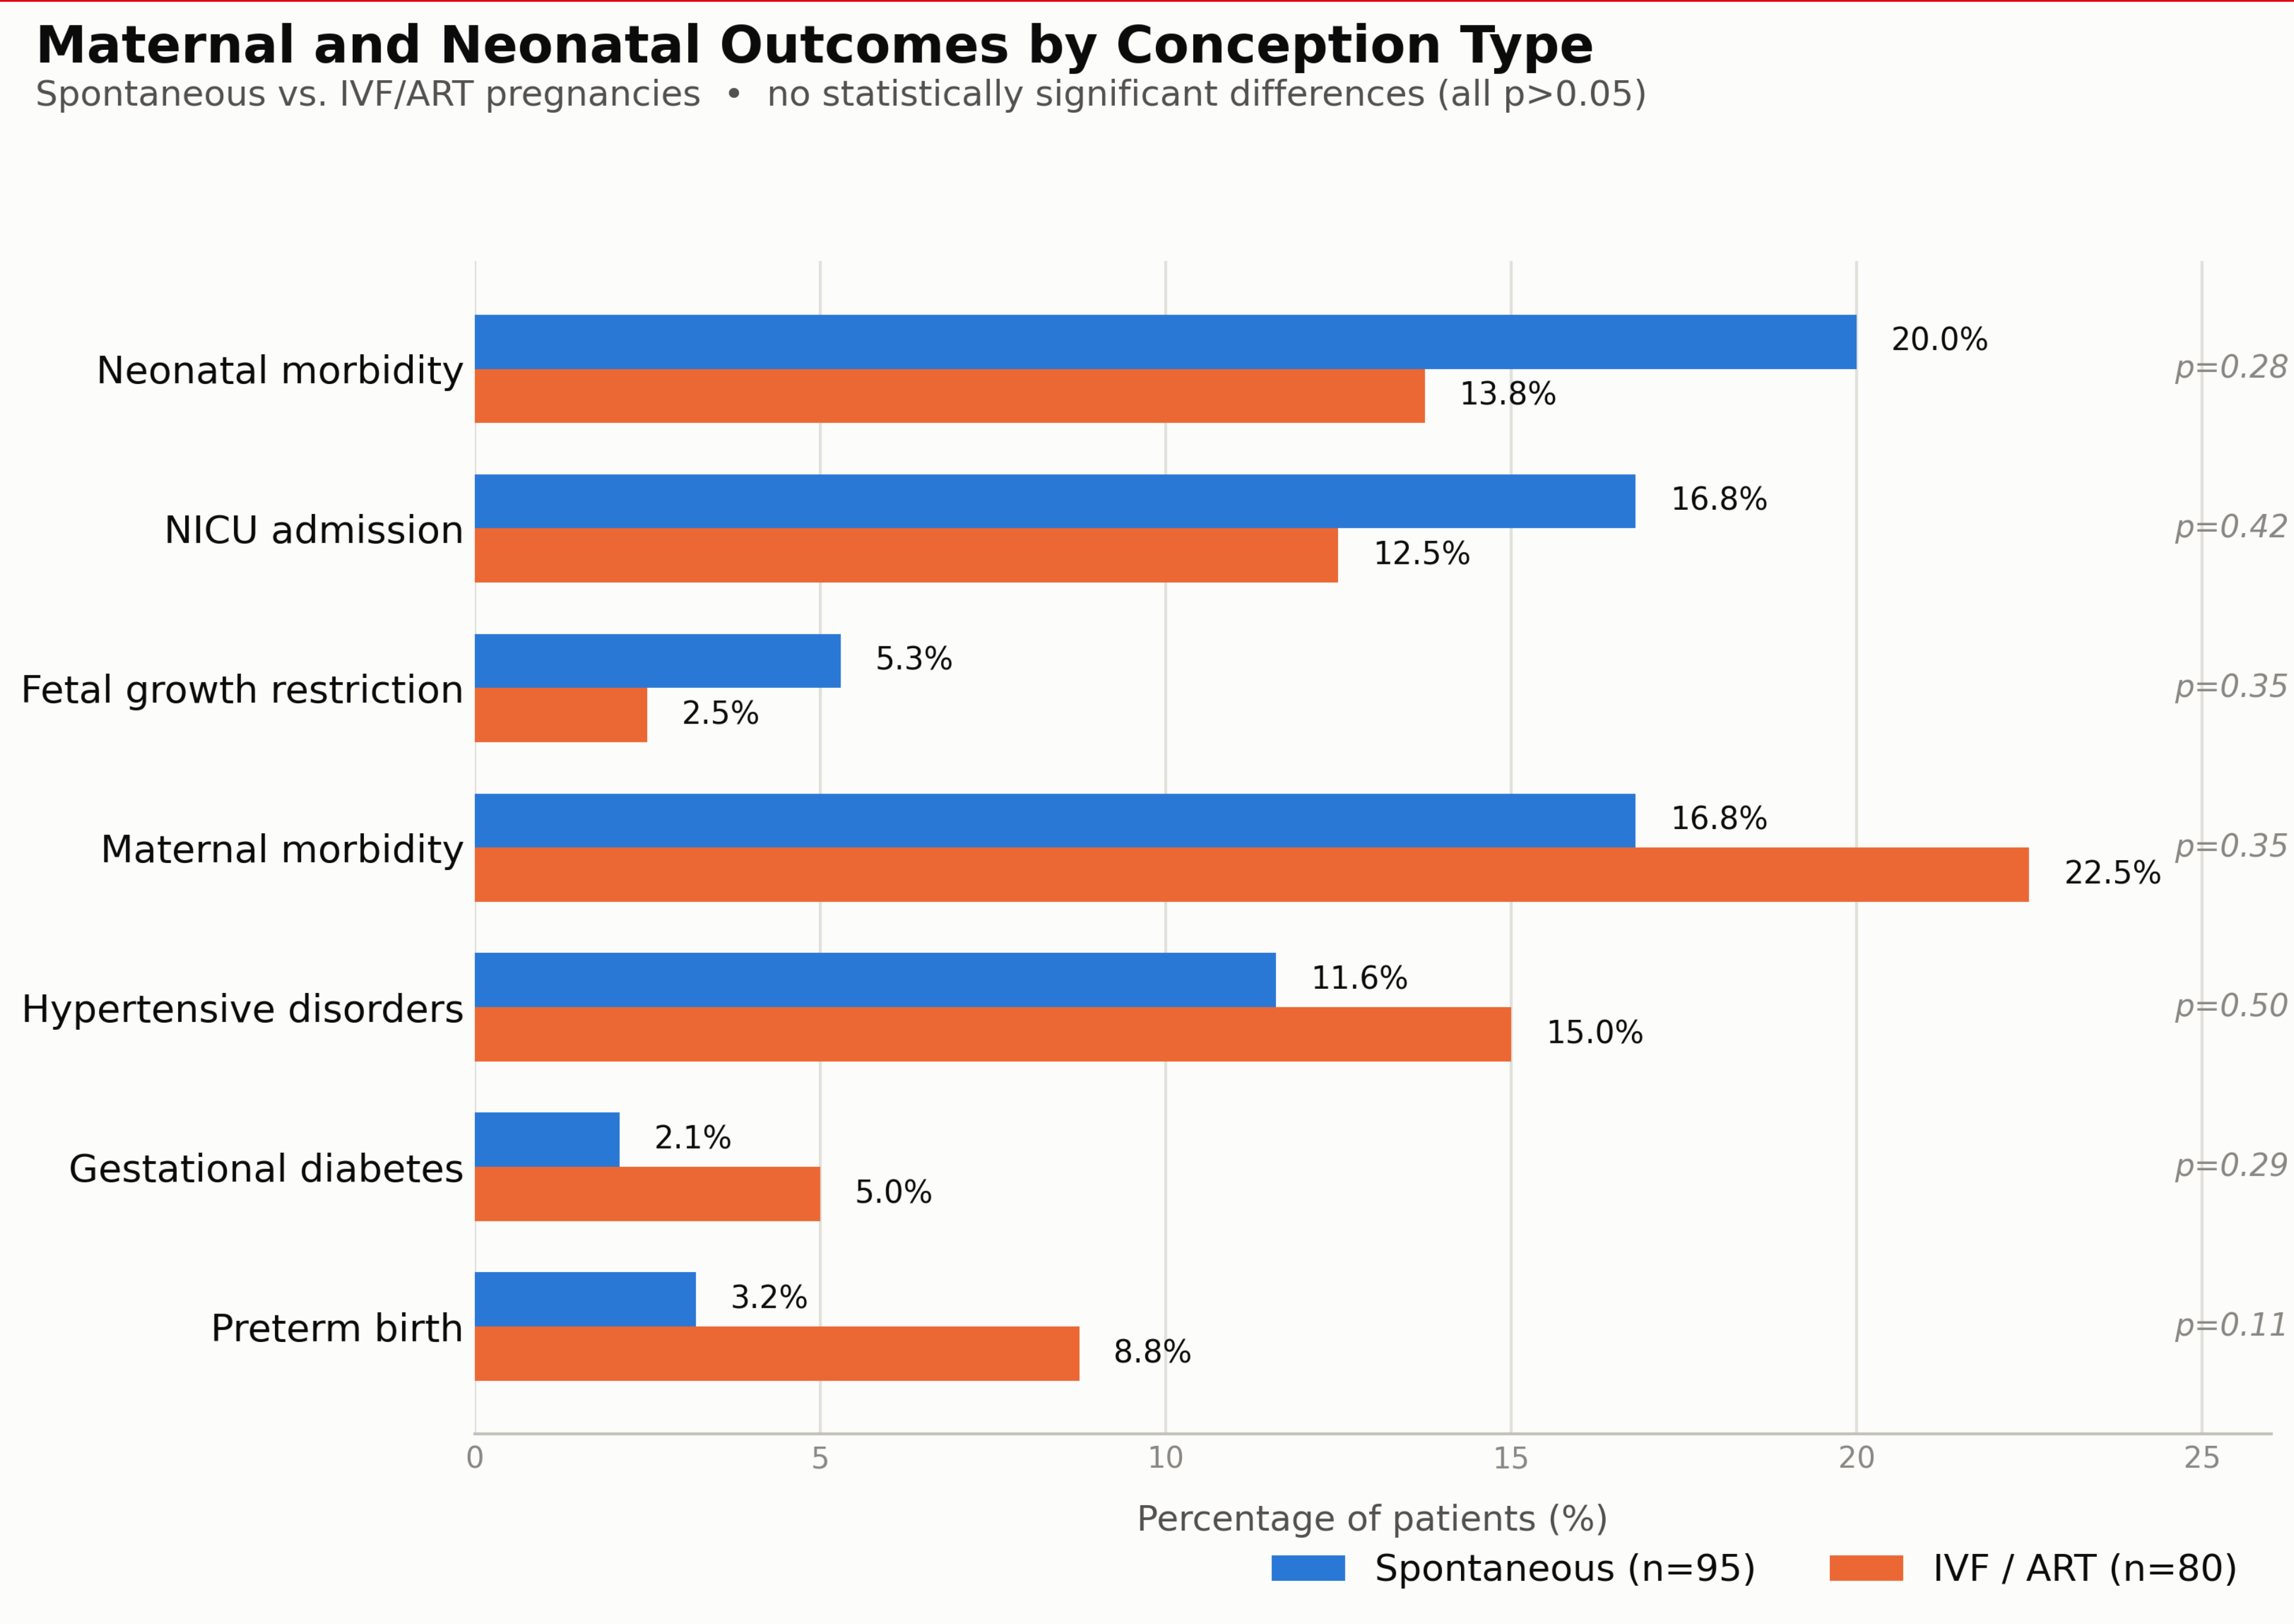

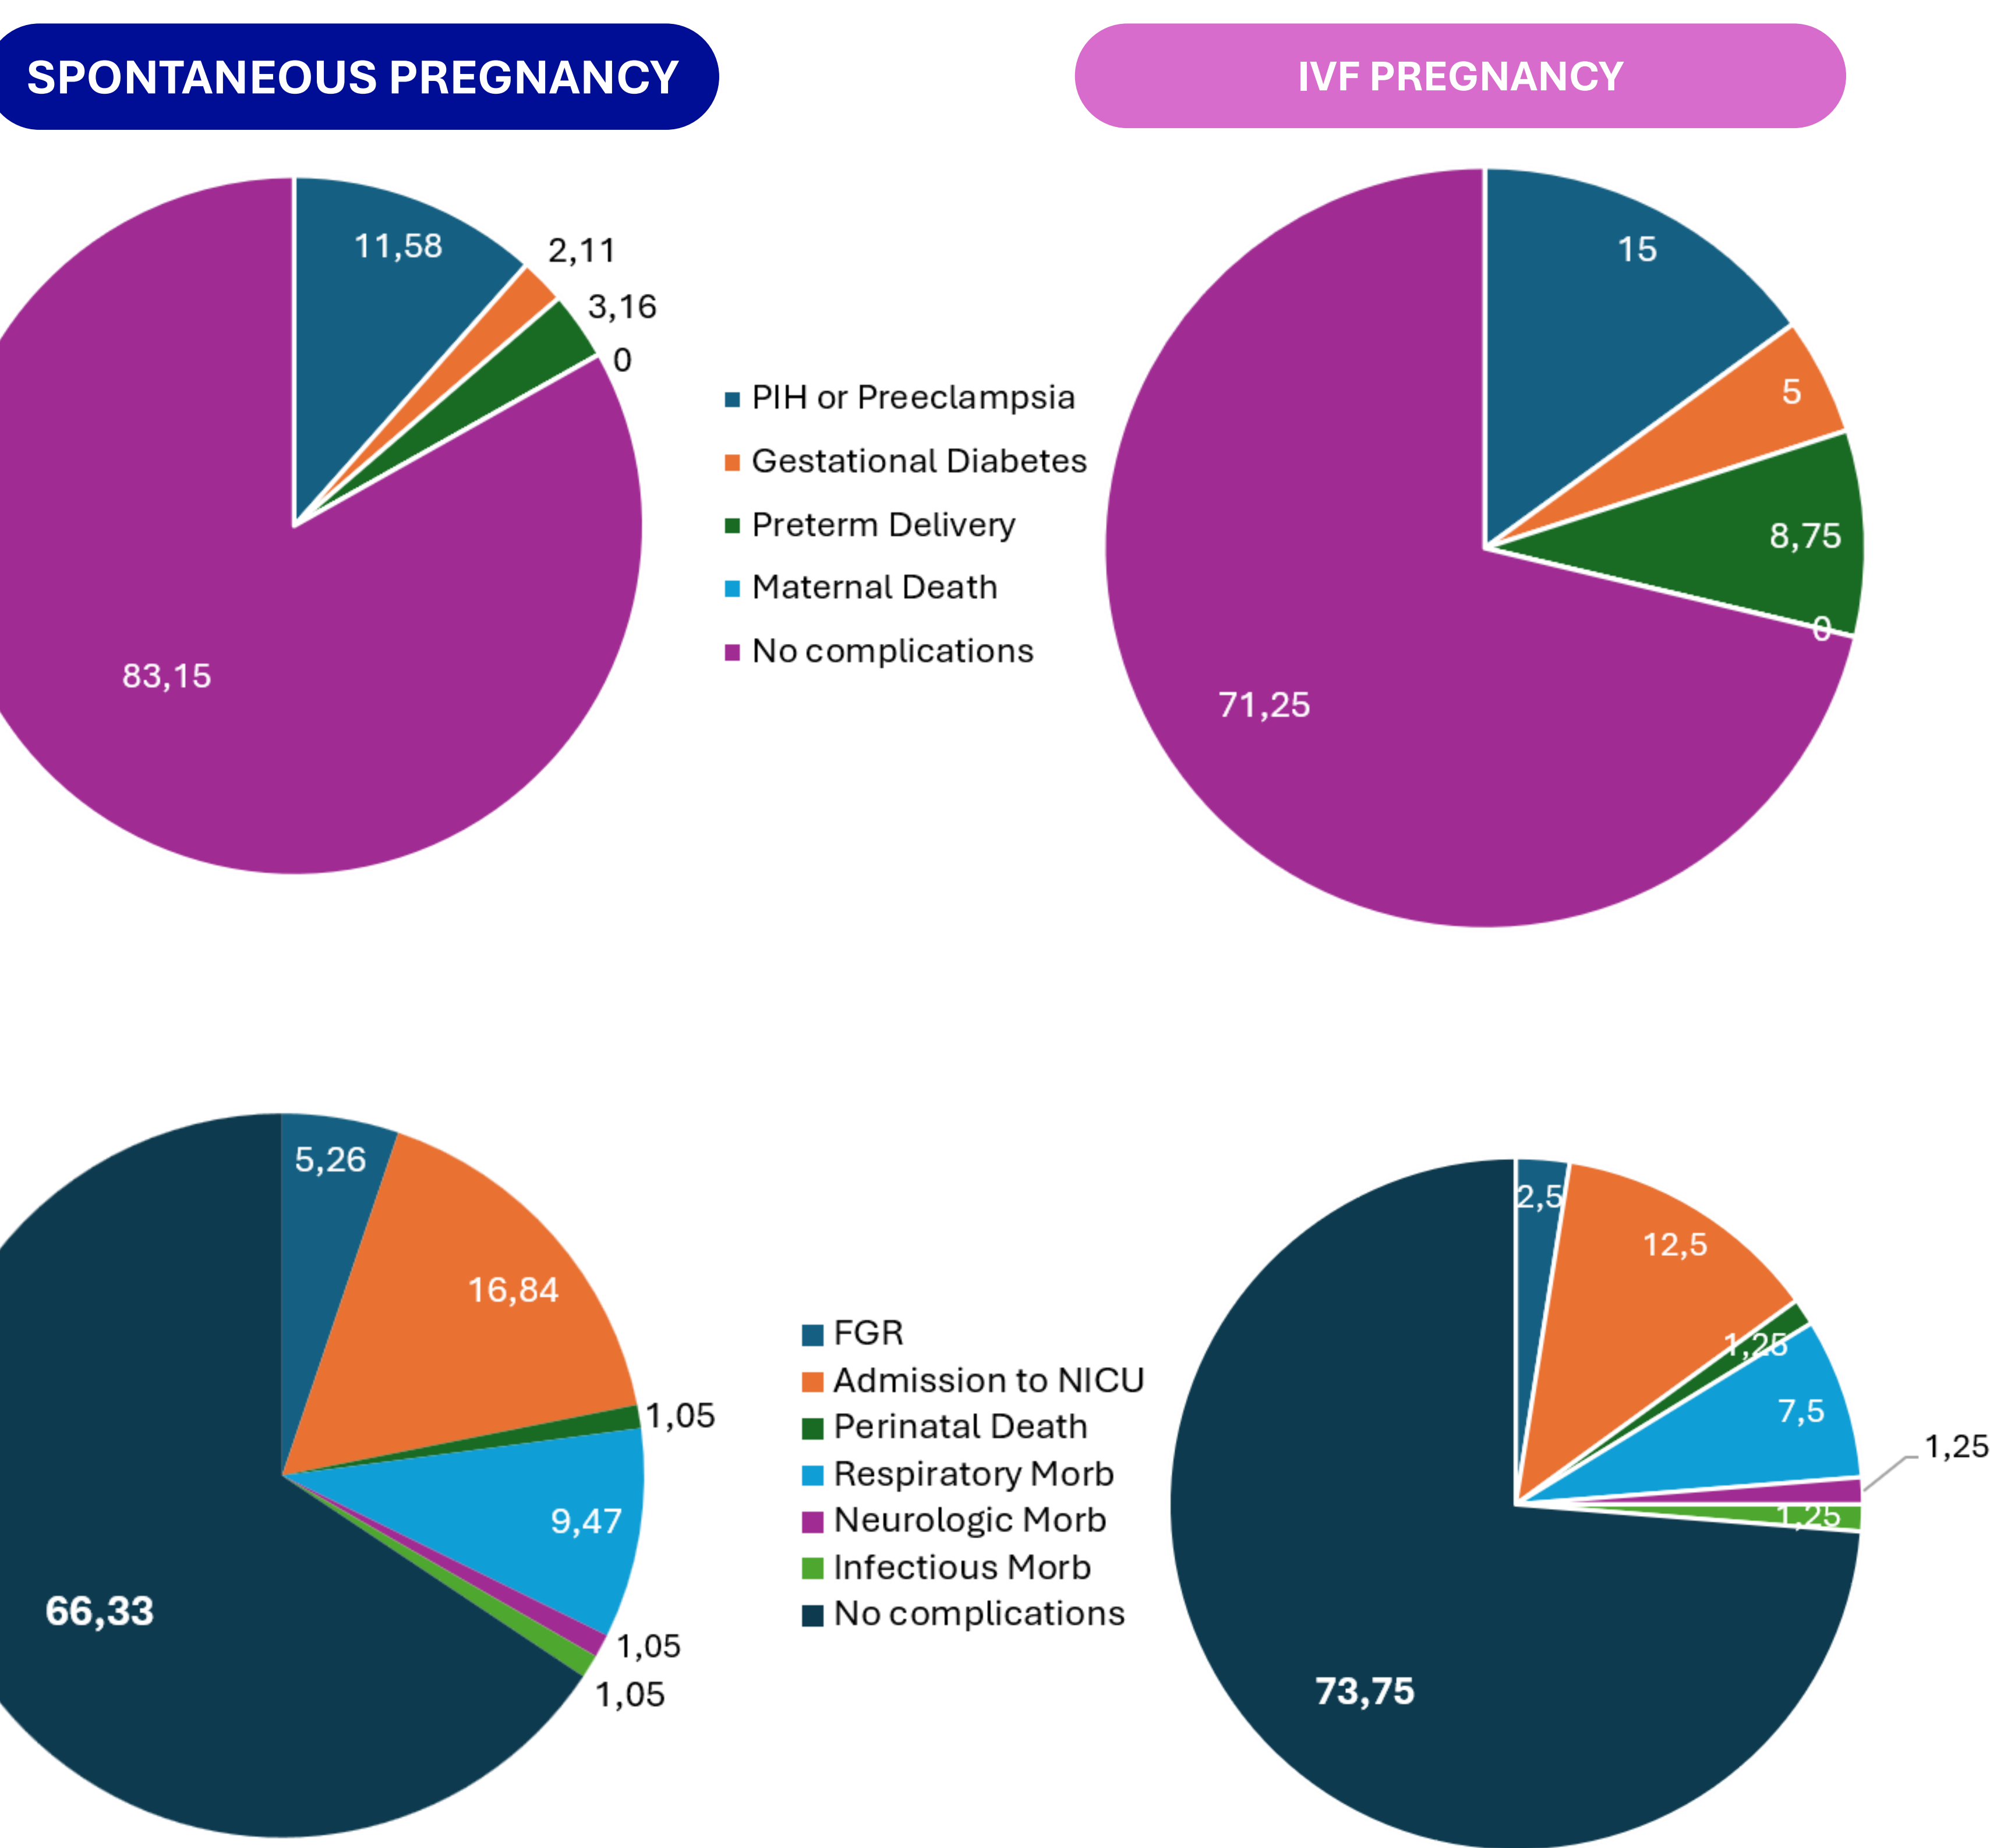

Objective

We designed a retrospective, observational study to compare obstetric and neonatal outcomes between women aged ≥ 40 years who conceived via in vitro fertilization (IVF) and those with spontaneous

Methods

Results

Conclusion

In women ≥40 years, no statistically significant association was found between mode of conception (IVF vs. spontaneous) and adverse obstetric or neonatal outcomes. Individualized risk assessment and preconception care, not conception method, appear to drive good perinatal outcomes.
