A common complication associated with implant restorations in the anterior maxilla is mucosal recession which compromises esthetic results and often leads to patient dissatisfaction. Implant malposition is one of the possible factors that can cause gingival recession, especially with wide diameter and buccally positioned implants. Various techniques have been proposed to correct soft tissue recession including prosthetic modifications, surgical management, or a combination of both. The present case report utilized a submerge technique and connective tissue graft to correct midbuccal recession present on a wide body implant restoration in the anterior maxilla.
