Trends in the Incidence of Colorectal Cancer in Transgender Patients in the United States

There are an estimated 7 million transgender Americans, with many having gender affirming surgery and/or hormone therapy. There are also no guidelines for colorectal cancer (CRC) screening in transgender patients, and evidence is lacking on rates of CRC compared to cis-gender patients.

NCBD reviewed 2004-2017 for rates of CRC and advanced disease (pathologic stages III and IV) by sex over time.

Aimed to stratify by sex: male (cis), female (cis), transexual-natal-male, or transexual-natal-female

No results available

No option for transgender in demographic data collection. No report on who is transgender or in transition.

Changes in data collection and reporting are needed to develop inclusive, comprehensive screening and prevention guidelines for CRC
